

Event-Driven Trading Framework

A practical guide and training outline for beginner, intermediate, and expert traders

Trade the repricing, not the headline.

BEGINNER

INTERMEDIATE

EXPERT

Educational use only

This guide is a framework for study and deliberate practice. It is not financial advice, not a promise of profitability, and not a substitute for independent research, risk controls, or compliance with your broker's rules. News trading can be fast, thin, and unforgiving. Paper trade first, size down on real events, and assume execution quality will be worse than your ideal chart.

The central idea is simple: markets do not move because information exists; they move because new information changes expectations. That means a trader's job is not to react to every headline emotionally. The job is to identify what matters, understand what the market expected, wait for the market to show how it is repricing risk, and only then execute with defined invalidation.

How information becomes price

News is only the trigger. The market reacts to the gap between what was expected and what the new information implies for policy, growth, earnings, or risk appetite.

Best mental model: trade the repricing after the market shows its hand. Retail traders usually do better on the accepted move than on the first violent spike.

Figure 1. A simple pipeline for translating information into a tradable reaction.

How to use this guide

Read this in layers. The first layer is market mechanics: learn why a release can be numerically 'good' and still produce a bearish reaction, or 'bad' and still rally. The second layer is execution: learn where a retail trader actually has edge, which is usually after the initial information shock, not during it. The third layer is professionalization: build a journal, tag event types, review your decisions, and prove that your process works over a meaningful sample.

This is not a call to trade everything. In fact, the guide argues the opposite. Fewer markets, fewer event types, and tighter process control tend to produce faster learning and cleaner statistics.

TL;DR: Markets move on surprises relative to expectations. Good news can sell off and bad news can rally. Beginners should focus on scheduled events, wait for confirmation, risk very small, and review every trade. Intermediate traders should build pre-event scenarios and combine catalysts with market structure. Expert traders think in terms of expectations, revisions, positioning, cross-asset confirmation, and regime.

One-page summary

- Trade the repricing, not the headline. The first question is always: what changed versus what the market expected?
- Prefer scheduled events for learning. If an event has a known release time, you can prepare scenarios, levels, and risk before price accelerates.
- Retail traders rarely need the first-second reaction. The cleaner opportunity is often the accepted move after the first burst of volatility.
- Your size should shrink as volatility, spread, uncertainty, or complexity increases.
- A release has layers: the headline number, revisions, composition, guidance, tone, and what the release implies for policy or earnings going forward.
- A good process beats a dramatic single trade. Track event type, scenario, execution model, slippage, and adherence.

Training outline at a glance

Phase	Goal	What you practice	Promotion test
1. Observation	Build cause-and-effect instincts	Track the calendar, note consensus and prior data, then record the immediate and delayed market reaction.	20+ annotated events with screenshots and notes.
2. Controlled execution	Trade one repeatable model	Use one instrument and one post-news setup; focus on timing, invalidation, and discipline.	20 planned trades with high rule adherence.

3. Scenario building	Think in probabilities, not opinions	Write bullish, bearish, inline, and no-trade outcomes before the release. Add cross-asset confirmation.	Positive expectancy or a clear improvement in decision quality by event type.
4. Expert integration	Trade regime and positioning	Blend macro narrative, comments, revisions, positioning, and multi-session follow-through.	A playbook with statistics, screenshots, and rules you can teach back clearly.

1. Market mechanics: why news moves price

TL;DR: A release matters when it changes the probability of future policy, growth, earnings, liquidity, or risk appetite. The number itself is only the beginning; the reaction depends on expectations, revisions, context, and positioning.

Think of every event as a comparison exercise. The market already has a baseline story before the release arrives. That story includes consensus expectations, prior data, what positioning looks like, and what participants care about most right now. When the new information lands, the market asks: is this stronger, weaker, hotter, colder, more hawkish, more dovish, or more threatening than what we already priced?

That is why 'good' news does not guarantee a rally. Strong growth can lift equities when the market wants growth, but the same data can hurt risk assets if it implies tighter policy, higher yields, or less chance of rate cuts. Likewise, weak data can be bearish if it signals deteriorating demand, or bullish if the market interprets it as opening the door to easier policy.

Professional interpretation usually has four layers. First comes the headline. Second comes the detail: revisions, wage growth, core components, guidance, margins, or the tone of the press conference. Third comes the cross-asset confirmation: rates, FX, sector leadership, credit, commodities, and volatility. Fourth comes the auction itself: does price accept the new level, reject it, or chop because the information was mixed?

- **Headline:** the most obvious number or announcement.
- **Composition:** the parts inside the release that often change the true meaning.
- **Revision:** prior data can be revised, sometimes changing the story more than the new number.
- **Implication:** what the release changes about policy, earnings, supply, demand, or sentiment.
- **Positioning:** a crowded trade can create a violent move even when the news is only modestly different from expectations.
- **Liquidity:** thin books widen spreads and increase slippage, especially in extended hours or around fast macro events.

Event-day workflow

The safest learning path is preparation first, observation second, execution third. Treat event days like a sequence rather than a single impulse decision.

Figure 2. A repeatable sequence for preparing, observing, executing, and reviewing event days.

2. The hierarchy of catalysts

Not all headlines deserve equal attention. Markets prioritize the information that best explains the current regime. In some periods the market cares most about inflation. In others, growth deterioration, liquidity, geopolitics, or earnings guidance dominates.

Beginner rule

Pick two or three event families and learn them deeply. Trying to trade every catalyst at once usually turns a promising process into noise.

Catalyst	What the market is asking	Markets usually most sensitive	Skill note
Inflation data (CPI, PCE, PPI)	Does this change the policy path or the discount-rate story?	Rates, FX, index futures, gold, growth sectors	Best studied with yields and the dollar beside your main chart.
Jobs / labor data	Is the economy overheating, slowing, or just normalizing?	Rates, USD, index futures, cyclical	Watch revisions, wages, participation, and not just payrolls.
Central-bank decisions and speeches	Is policy more hawkish, dovish, or uncertain than expected?	Rates, FX, indices, gold	Tone and Q&A can matter as much as the statement.
Growth data (GDP, PMIs,	Is demand strengthening or	Indices, bonds,	Growth-sensitive reactions

ISM, retail sales)	fading?	commodities, cyclicals	change a lot by regime.
Earnings and guidance	Did cash-flow expectations improve or deteriorate?	Single stocks, sectors, index components	Guidance and margins often matter more than the headline EPS beat.
SEC filings / management comments / 8-Ks	Was there a material event that changes the company's outlook?	Single stocks, peers, sector sympathy	Read the actual filing when possible; summaries can miss key caveats.
Geopolitical and policy shocks	Does this change supply, trade, risk appetite, or safe-haven demand?	Oil, gold, FX, indices, defense or transport names	Binary or fuzzy stories require more patience and smaller size.

3. Beginner framework

TL;DR: The beginner's edge is not speed. It is preparation, waiting, simplicity, and smaller size. Learn scheduled events, trade only liquid instruments, avoid the first-second scramble, and journal every attempt.

A new trader should treat news as a study of cause and effect before treating it as a source of profit. The goal is to recognize what kind of information moves your market, when that market tends to react most cleanly, and how the auction behaves after the first burst of volatility.

For beginners, the safest structure is a scheduled event on a highly liquid product. That could be an index future, a liquid ETF, or a major forex pair, depending on your market and access. Avoid illiquid small caps, thin options chains, or products where wide spreads make even a correct idea expensive to express.

The best beginner model is usually a reaction-and-acceptance trade. You let the initial release hit, let the first emotional move print, and then ask whether the market is actually accepting the new direction above or below a meaningful level. Acceptance can look like a break and hold, a pullback that respects the new zone, or repeated failure to reclaim the old range.

- Know the event time, the prior data, and the consensus number before the release.
- Know why the event matters. If you cannot explain what the market cares about, you are guessing.
- Mark simple levels: prior day high and low, overnight range, obvious swing highs and lows, and the pre-release range.
- Decide your maximum dollar loss before the release.
- Wait for the market to choose a direction and hold it; avoid pressing buttons during the fastest spike.
- If spreads widen materially or the move becomes disorderly, do not force it.
- Stop after your daily loss limit. Event days can create revenge-trading spirals very quickly.

A safe beginner template

Event hits -> first impulse prints -> price breaks and holds beyond the event range -> pullback respects the new direction -> enter with risk beyond invalidation -> scale or trail according to structure.

4. Intermediate framework

TL;DR: Intermediate traders stop asking 'up or down?' and start asking 'which outcome creates continuation, rejection, or chop?' Their edge comes from scenario planning, market structure, relative strength, and disciplined execution models.

At the intermediate level, you should arrive at an event with multiple scenarios already written down. A hot inflation number, a soft inflation number, and an in-line number do not deserve the same plan. The same is true for earnings beats, misses, and guidance changes. Pre-event scenario work reduces emotion because you are responding to a prepared map instead of improvising under stress.

Intermediate traders also combine catalysts with structure. A bullish release that lands into a major resistance area can still fail. A bearish release that cannot break a key support zone can create a reclaim. Price structure tells you

whether the new information is being accepted or whether the market is using the headline as liquidity before moving the other way.

Relative strength and cross-asset reads start to matter here. For example, if inflation lands hot, are short-end yields confirming higher? Is the dollar firm? Are rate-sensitive sectors lagging? If the confirmation is missing, the move may be less trustworthy or less persistent than it first appears.

1. Write four outcomes before the event: bullish, bearish, in-line, and no-trade.
2. Define which other market should confirm the move: yields, DXY, sector leaders, crude, gold, or credit.
3. Pick one execution family in advance: continuation, fade after failure, or delayed trend.
4. Know your invalidation before entry. The stop belongs where the trade idea is wrong, not where the pain becomes emotional.
5. Review whether the reaction matched the scenario or whether the market cared about something else.

Question before the event	Why it matters
What does the market care about today?	A growth market and an inflation market can react very differently to the same print.
What is already priced in?	The market can punish traders who are late to an obvious story.
What would confirm the move?	Cross-asset agreement reduces false conviction from a single chart.
What makes it a no-trade?	A written kill condition prevents you from forcing an entry because you prepared.
Which level proves acceptance?	Without a level, you are trading emotion instead of structure.

Three reaction models worth mastering

Most event-driven trades fit one of three families. Learn the structure, then match the event to the model instead of forcing the same entry every time.

Figure 3. Three common event-driven price behaviors: continuation, spike-and-fade, and delayed trend.

5. Expert framework

TL;DR: Expert news trading is expectation trading. The edge is not just faster reaction; it is better interpretation of what is priced, what changed, what the market now believes comes next, and when the best trade is to do nothing.

Advanced traders think in layers of information and time. They care about the consensus number, but also the whisper number, revisions, positioning, and the policy or cash-flow implications that follow from the data. They know that some events are first-order information shocks, while others are second-order interpretive events where the press conference, Q&A, management commentary, or geopolitical follow-up carries more weight than the original headline.

They also think in regimes. When inflation is the dominant axis, a 'strong' growth number may be bearish for long-duration assets because it pressures yields. When growth fears dominate, the same number can be supportive. When geopolitical risk dominates, safe-haven flows, supply risks, and policy responses can matter more than ordinary cyclical logic.

At the expert level, you should separate immediate reaction from durable repricing. The first minute may be about stops and algorithms. The next thirty minutes may be about confirmation. The next several sessions may be where the true narrative shift expresses itself. Experts are often willing to miss the first burst if it improves the quality of the second or third decision.

- Expectations: what was consensus, what was whispered, and how was the market positioned?
- Composition: which subcomponent or comment changes the policy, growth, or earnings path most?
- Cross-asset confirmation: does the move agree with rates, FX, sectors, and volatility?
- Regime: what axis dominates right now—growth, inflation, liquidity, policy, or geopolitics?
- Time horizon: is this a scalp, an intraday auction, or a multi-session repricing event?

- Selectivity: is the edge better in the product you first looked at, or somewhere else in the chain?

Regime map: growth vs. inflation

The same headline can produce different reactions depending on what the market cares about most. A simple regime map keeps your interpretation grounded.

Figure 4. A simple regime map helps explain why identical headlines can create different reactions.

Expert habit

Build a playbook around event types and regimes, not around isolated outcomes. 'Hot CPI in an inflation-sensitive regime' is a playbook. 'That one day I caught a big spike' is a memory, not a process.

6. Event preparation worksheet

TL;DR: If you want cleaner execution, make more decisions before the event and fewer during the heat of the move.

Use a fixed worksheet before high-impact events. The point is not paperwork for its own sake; it is to move thinking out of the emotional moment. A prepared trader usually makes fewer, clearer decisions.

Field	What to write
Event / time	The exact release, session, and instrument you will watch.
Why it matters	What policy, earnings, growth, supply, or sentiment question the event can answer.
Consensus / prior	The baseline story already in the market.
Primary levels	Overnight high/low, prior day high/low, obvious swing points, VWAP or equivalent reference.
Scenario A	What outcome is bullish? What should confirm it? How would you enter?
Scenario B	What outcome is bearish? What should confirm it? How would you enter?
Inline / mixed	What if the number is close to expectations or contradictory inside the details?
No-trade conditions	Wide spread, no confirmation, conflicting instruments, binary geopolitics, or no clean level.
Risk plan	Maximum dollar loss, maximum number of attempts, and daily stop.

Seven questions to ask before every event:

6. What is the market actually focused on today?
7. What is already expected and what would count as a real surprise?
8. Which related market should confirm the move?
9. Where is the acceptance or failure level?
10. Am I planning a continuation trade, a fade after failure, or a delayed trend trade?
11. What makes this a no-trade?
12. How much can I lose if I am wrong immediately?

Decision tree: trade it or leave it alone?

Not every event deserves a trade. The fastest way to improve is to filter aggressively and only act when the market gives you a tradable structure.

Figure 5. A filtering tree for deciding whether to trade, wait, or stand aside.

7. Execution models for retail traders

There are many ways to structure a news trade, but a practical framework is to match the event to one of a small number of execution families. Each family solves a different problem.

Model	Best used when	Core idea	Common mistake
Acceptance continuation	Clear macro surprise, strong guidance, decisive breakout	Wait for price to break and hold beyond a meaningful level, then enter on confirmation or pullback.	Chasing the first candle before acceptance is visible.
Spike and fade	Emotional overreaction, exhaustion, no confirmation, or failed breakout	Let the first move overextend, then look for reclaim or rejection before fading.	Shorting strength or buying weakness too early.
Delayed trend	Mixed release, press conference or call matters more, market needs time	Wait for a later structure break once the narrative becomes clearer.	Assuming the move is over because the first impulse was messy.
Multi-session follow-through	True regime change in policy, growth, earnings, or geopolitics	Trade the pullbacks over several sessions rather than forcing the initial burst.	Oversizing overnight exposure without a tested plan.

A useful mental reset

Your job is not to predict every spike. Your job is to choose the market behavior you understand best and let other behaviors pass without emotional cost.

8. Risk management on event days

TL;DR: Event-day risk management is different from ordinary-session risk management. Volatility is higher, fills are worse, and conviction can become dangerous if size is not reduced.

The first rule is simple: when uncertainty or speed rises, size should generally fall. A setup that looks attractive on the chart can still be a bad trade if spreads are too wide, the order book is too thin, or your broker's execution rules make the product hard to control.

Know your order types. In stocks, a stop order becomes a market order once triggered, which means the execution price can be materially different from your stop price in volatile conditions. In extended hours, liquidity is thinner and prices can be less competitive across venues. If you use margin or leverage, losses can expand faster than you expect.

- Risk less per trade on event days than on ordinary-session setups unless you have strong data proving otherwise.
- Use invalidation-based stops, not arbitrary 'pain thresholds.'
- Expect slippage in your planning. The chart will always look cleaner than the fill.
- Set a daily loss cap and honor it. News can invite multiple revenge attempts in the same hour.
- Avoid stacking correlated bets unless the strategy explicitly calls for that exposure.
- If the event occurs in extended hours, remember that liquidity and order quality may be materially worse.

Simple sizing formula

Position size = maximum dollar risk divided by the distance from entry to invalidation. If execution quality is likely to be poor, widen the assumed stop or cut the size further.

A practical training rule is to think in R rather than dollars. If your maximum planned loss on the setup is 1R, the day should end if you lose your pre-defined number of R. That forces process discipline instead of emotional escalation.

9. Cross-asset interpretation

A single chart can be persuasive and still be wrong. Cross-asset confirmation keeps you from over-believing the first move. The exact relationships change by regime, but the discipline remains valuable: if you are trading an event because it changes the macro story, check whether related markets are behaving as that story would suggest.

Catalyst	Typical first read	Useful confirmation	Common trap
Hotter inflation	Higher yields, stronger dollar, pressure on long-duration risk	Short-end rates, DXY, growth-sector weakness	Treating a strong payroll or growth print as automatically bullish

			without checking the rate reaction.
Softer inflation	Lower yields, easier policy expectations, relief in growth assets	2-year yields, dollar softness, semiconductor or tech leadership	Buying the first relief spike when the move is not being confirmed elsewhere.
Weak growth data	Bond support, cyclical pressure, defensive rotation	Treasury reaction, sector rotation, oil weakness	Assuming weak data always bullish because it may imply easier policy later.
Strong earnings beat + guidance raise	Stock reprices higher, peers may sympathy-move	Volume, sector breadth, analyst revisions, conference-call tone	Focusing on EPS only while guidance or margins deteriorate.
Supply or geopolitical shock	Commodity moves, safe-haven demand, risk-off pressure	Oil, gold, CHF/JPY, index breadth	Forcing a directional equity view before the market has priced the transmission channel.

Important nuance

Cross-asset confirmation is not a magic checklist. It is a way to pressure-test your interpretation. When it disagrees with your idea, either reduce confidence or wait.

10. Trading stock-specific news

TL;DR: For individual stocks, the real signal is often in guidance, margins, conference-call tone, or the actual filing—not just the headline beat or miss.

Single-stock news is more idiosyncratic than broad macro trading. A company can beat on revenue and EPS but still sell off because guidance disappointed, margins compressed, a key segment weakened, or management used cautious language on the call. Conversely, a miss can rally if the market expected worse and forward commentary improves.

Use the actual source when possible. Press summaries are useful, but SEC filings, company releases, and conference-call commentary often reveal what the fast headline omits. Material current events, guidance, executive changes, financing actions, legal issues, or other significant developments may appear in Form 8-K filings or in related investor-relations disclosures.

- Check whether the company is trading in regular hours or extended hours; the risk profile is not the same.
- Compare headline results to guidance, margins, and segment detail.
- Watch opening range behavior and relative volume once the regular session begins.
- Check sector sympathy: strong or weak peers can reinforce or dilute the move.
- Be cautious with options around earnings; being directionally right does not guarantee profit if implied volatility collapses after the event.

What to verify	Why it matters
Guidance	Forward outlook often drives the durable repricing more than the backward-looking quarter.
Margins and segment detail	A headline beat can hide deterioration in the most important part of the business.
Conference-call tone	Management confidence, caution, or changing priorities can alter the narrative.
Volume and liquidity	Thin pre-market moves can look huge but fail once regular-session liquidity appears.
Peer reaction	Sympathy moves can confirm that the event matters beyond one ticker.
Halt and gap risk	High-volatility names can become untradeable if the spread, halt risk, or gap size overwhelms your plan.

11. Geopolitical, policy, and narrative trading

TL;DR: Narrative shifts are rarely as clean as scheduled data. The edge comes from mapping scenarios,

identifying the transmission path, and being willing to wait for the story to become tradable.

Geopolitical and policy stories usually unfold in waves. The early headlines are often emotional, fragmented, and hard to size. That is why experienced traders focus on the transmission path. Does the development change supply? Demand? Trade routes? Safe-haven demand? Policy response? Inflation risk? Growth risk? If you cannot name the path, the move may be more emotional than investable.

These events are also a good place to separate binary from fuzzy information. A central-bank statement or a specific tariff announcement can be relatively binary. A cloud of rumors, threats, negotiations, and anonymous sourcing is much fuzzier. The fuzzier the implication, the more selective you should become.

- Map the most direct effect first, then the second-order effects.
- Identify which assets should react first: oil, gold, defense names, transport, safe-haven FX, or broader indices.
- Assume whipsaw risk is high when information is incomplete.
- Do not confuse urgency with opportunity. Some of the best narrative trades occur after the initial shock, not during it.
- When in doubt, reduce size dramatically or stand aside.

12. Journaling and proving it is not luck

TL;DR: Skill is not proven by a dramatic week. It is proven by repeatable decisions over a meaningful sample, recorded honestly and reviewed without excuses.

Event-driven trading can feel deceptively skillful because a single release can create an outsized win. That is exactly why a journal matters. The journal separates process from outcome. You need to know whether your entries were well-timed, whether your scenario work was right, whether your fills were realistic, and whether the setup family actually has expectancy.

Track more than P&L. Event type, regime, confirmation, slippage, and rule adherence often tell you more than the money made on one trade. A trader who followed the plan and lost can be improving. A trader who broke every rule and won may only be rehearsing a future drawdown.

Core expectancy formula

Expectancy = (win rate × average win) – (loss rate × average loss). A strategy does not need a high win rate if its average winner is meaningfully larger than its average loser.

Journal field	Why it matters
Event type	Lets you discover which releases you actually understand.
Market regime tag	Shows whether your edge depends on inflation, growth, risk-off, or other dominant themes.
Scenario written before event	Proves whether the trade came from preparation or improvisation.

Execution model	Continuation, fade, delayed trend, or multi-session follow-through.
Entry, stop, target, actual fill	Separates chart fantasy from executable reality.
Slippage / spread conditions	Identifies whether poor execution is killing good ideas.
MFE / MAE	Shows whether you are entering too late, exiting too soon, or holding poor trades too long.
Rule-adherence grade	Decision quality matters even when P&L is noisy.

13. 30 / 60 / 90-day training plan

A strong training plan narrows variables. Do not add more products, more models, or more leverage just because one week went well.

Window	Focus	Daily / weekly work	Target outcome
Days 1-30	Observation and vocabulary	Track scheduled events, write the basic market story, screenshot the reaction, and build a glossary. Paper trade only or trade micros/minimum size if already experienced.	Understand what different event families tend to move and when to stay out.
Days 31-60	One setup, one product	Trade only one repeatable post-news model in one liquid market. Keep a strict risk cap and review every execution.	Consistency in preparation and execution quality.
Days 61-90	Scenario building and cross-asset reads	Add written scenarios, confirmation markets, and regime tags. Review trades by event type, not just by day.	A clear sense of what you actually do well and what should be removed.
Beyond 90 days	Playbook refinement	Expand only after you have statistics. Add second products or multi-session holds carefully.	A compact playbook that survives review, not just momentum.

- Daily routine: check the calendar, mark key levels, write scenarios, define no-trade conditions, set risk.
- Weekly routine: review screenshots, classify setups, and separate process errors from market noise.
- Monthly routine: update your playbook, remove low-edge behaviors, and measure expectancy by event type.

14. Common mistakes and their fixes

Mistake	Why it happens	Fix
Trading every headline	FOMO and lack of a defined catalyst hierarchy.	Specialize in a few event families and ignore the rest.
Treating good news as automatically bullish	Failure to think about expectations and policy implications.	Always compare the result to what was priced and what it changes next.
Oversizing into volatility	Greed, recency bias, and	Use a smaller event-day size and a

	underestimating slippage.	hard daily loss cap.
Fading the first spike blindly	Ego and the desire to catch the exact turn.	Wait for failure structure and confirmation before fading.
Ignoring revisions or subcomponents	Surface-level reading of the release.	Read past the headline and note which details the market cares about most.
Using illiquid instruments	Attraction to dramatic percentage moves.	Prefer liquid futures, ETFs, or heavily traded names when learning.
Confusing a lucky result with a strong process	Outcome bias.	Grade rule adherence and track expectancy across many trades.
No written no-trade condition	Compulsion to participate.	Define what invalidates the setup before the event starts.

Final discipline rule

Standing aside is a position. If the market is unclear, your safest edge may be information gathering rather than execution.

15. Glossary and official source base

Glossary

Consensus: The market's baseline expectation before a release.

Revision: A change to prior data that can alter the story more than the new print.

Guidance: Forward-looking management commentary or projections.

Hawkish / dovish: Language implying tighter or easier policy, respectively.

Spread: The difference between the current bid and ask.

Slippage: The gap between your expected execution price and the actual fill.

Acceptance: Price holds and builds in the new direction instead of immediately reversing.

Rejection: Price cannot hold the new zone and snaps back through it.

Relative strength: How one asset or sector behaves versus another or versus the broader market.

Risk-on / risk-off: A loose description of whether markets are favoring growth/risk assets or defensive/safe-haven behavior.

IV crush: A drop in implied volatility, often after earnings or binary events, that can hurt option buyers.

Official source base for independent study

Use primary sources whenever possible. They are slower to read than social media, but they reduce misunderstanding and help you see what the market is actually reacting to.

[U.S. Bureau of Labor Statistics — CPI](#)

[U.S. Bureau of Labor Statistics — Employment Situation](#)

[U.S. Bureau of Labor Statistics — release schedules](#)

[Bureau of Economic Analysis — GDP](#)

[Federal Reserve — FOMC](#)

[Federal Reserve — FOMC calendars and statements](#)

[SEC — Form 8-K](#)

[SEC — Regulation FD / selective disclosure](#)

[NFA — forex regulatory guide and slippage policies](#)

TL;DR: The durable edge in event-driven trading comes from knowing what matters, planning scenarios before the release, waiting for the market to show acceptance or failure, controlling risk relentlessly, and reviewing enough data to separate skill from luck.
