

Support & Resistance Pattern Guide

A detailed visual handbook built from the chart and support / resistance concepts shown in the YouTube video **TOP 9 Support & Resistance SECRETS (MUST WATCH!)**.

This guide turns the video examples into a structured reference: what each pattern means, when it tends to work best, what confirms it, how to define invalidation, and what to avoid.

What is inside: 9 pattern pages, a quick-reference matrix, level-drawing rules, and practical trade-management recommendations.

Breakout logic

Reversal logic

Trap / filter logic

Educational use only - this is a pattern-study guide, not personal investment advice.

How to read support and resistance

The strongest levels are usually obvious, visible on higher time frames, and paired with the right kind of price behavior. In practice, the level itself is only part of the story - the approach, the reaction, and the available room to the next level matter just as much.

1. Draw zones, not razor-thin lines

Support and resistance usually behave like areas. Clustered wicks and repeated reactions often define a zone better than a single exact price.

2. Prioritize the cleanest multi-touch levels

When a level is obvious from a zoomed-out chart, more participants are likely to see it. Clean levels often matter more than crowded micro-levels.

3. Judge the approach, not just the touch

Compression, power moves, triangles, stair-step climbs, and failed breakouts all change the odds. The same level can imply a very different trade depending on how price arrives.

4. Demand confirmation and know invalidation

Use body closes, rejection candles, retests, or structure breaks for confirmation. Before entering, define exactly where the idea is wrong and where the first target sits.

Practical takeaway: Do not ask only “where is support or resistance?” Also ask: Is the level clean? Is price compressing, exploding, grinding, or trapping? What exact price action will confirm the idea? And if the idea fails, where is the invalidation?

What usually gives a level more weight

- Higher-time-frame origin, such as daily, weekly, or monthly structure
- Multiple clean touches that cluster in the same area
- Long time away before the first meaningful retest
- Confluence with trend structure, moving averages, or prior role reversal
- Open space to the next opposing level

What often makes a level less reliable

- Mid-range noise with no meaningful reaction history
- Too many overlapping lines and no clear hierarchy
- Nearby levels that crowd the profit path immediately
- First-touch fades after a messy stair-step grind into the level
- No clear trigger, no clean invalidation, or no room to target

The next page summarizes the nine patterns at a glance. After that, each pattern gets its own dedicated page with context, confirmation, recommendations, and risk notes.

Quick-reference matrix

Use this page as the fast triage layer. It tells you whether a pattern is primarily a breakout, reversal, retest, trap, or caution filter - and what must happen before the idea earns a trade.

Pattern	Bias	Type	Typical trigger	Skip if
Build-up at resistance + MA support	Bullish	Continuation	Close above or hold on retest	Pullbacks start cutting under the build-up
Clean multi-touch levels	Neutral	Filter	Reaction at an obvious zone	Chart is cluttered or crowded
Descending triangle into support	Bearish	Breakdown	Close below support / failed retest	Only a wick break; fast reclaim
Time-away retest of HTF level	Conditional	Retest	Fresh rejection or acceptance	No clear reaction on revisit
Ascending triangle into resistance	Bullish	Breakout	Close above resistance / hold retest	Triangle is loose or overextended
Resistance rejection after power move	Bearish	Reversal	Bearish close after rejection	Price starts compressing under resistance
Support rejection after power move	Bullish	Reversal	Bullish close after hammer / rejection	Weak bounce back under support
Choppy stair-step approach	Caution	Filter	Require extra structure break	Shorting because of the first touch alone
Bull trap above resistance	Bearish	Trap	Close back inside range / failed retest	Price accepts above the breakout line

Reading the matrix: “Bias” tells you the directional lean. “Type” tells you the job of the pattern. “Typical trigger” is the minimum confirmation. If the “Skip if” column is already true, pass on the setup and wait for something cleaner.

Breakout patterns Build-up + moving-average support and ascending / descending triangles. These need acceptance through the level, not just a touch.	Reversal patterns Support or resistance rejection after a power move. These work best when the move into the level looks stretched and emotional.
Retest patterns Time-away retests focus on old higher-time-frame levels. The first clean revisit after long time away often deserves extra attention.	Trap / filter patterns Bull traps create failure trades. Choppy stair-step approaches are mostly warnings to demand more confirmation and avoid forcing the first-touch fade.

Pattern 1 of 9 | Bullish continuation / breakout bias

Build-up at resistance with moving-average support

Bullish continuation setup

**What it signals**

Price pauses directly beneath a clear resistance zone, but the pullbacks stay shallow and dynamic support - often the 20 or 50 moving average - keeps catching price. That combination suggests buyers are absorbing supply instead of backing away.

Best context

- Established uptrend or strong impulse already in place
- Resistance is obvious on a zoomed-out chart
- Pullbacks are brief and do not retrace deeply
- Moving averages are rising beneath the build-up

Confirmation checklist

- Candles tighten near resistance instead of rejecting hard
- Repeated holds above the same short-term support shelf
- A decisive close above the resistance zone
- Best follow-through comes when the breakout is not already overextended

How to trade it

- **Conservative entry:** Buy the first close above resistance, or the first retest that holds above it.
- **Aggressive entry:** Scale in during the compression only if the level is very clean and the trend is already strong.
- **Protective stop:** Below the build-up lows, or below the last swing low / moving-average support cluster.
- **First target:** The next resistance level, or a measured move roughly equal to the height of the base.

Risk and invalidation

- Skip if pullbacks start slicing through the moving averages
- Skip if the breakout candle is huge and far from the invalidation point
- If price breaks out and instantly falls back under the zone, treat that as a warning

Recommendation: Prefer this setup when price spends time under resistance without giving much back. It is often stronger than a breakout that comes after a deep pullback because the market is showing demand right in front of the level.

Pattern 2 of 9 | Level selection filter / quality control

Wrong: cluttered chart

Too many levels = analysis paralysis

**Better: obvious multi-touch levels**

Zoom out, keep only the cleanest zones

**What it signals**

This is not a single entry pattern - it is the filter that improves every support and resistance trade. Clean, obvious, multi-touch zones usually matter more than a clutter of minor lines because more participants are likely to notice and react to them.

Best context

- The level is visible even after zooming out
- Two or more meaningful reactions happen near the same area
- Clustered wicks are treated as a zone, not as separate lines
- There is clear room between this level and the next major level

Confirmation checklist

- You can explain the level in one sentence
- The line or zone can be adjusted slightly to capture the real reaction area
- The chart does not contain dozens of competing levels
- Higher-time-frame levels get priority over minor intraday noise

How to trade it

- **Conservative use:** Wait for price-action confirmation when price reaches the clean zone.
- **Aggressive use:** Only consider first-touch trades if the level is extremely obvious and trend context supports it.
- **Protective stop:** Beyond the far side of the zone - not directly on the dashed line.
- **First target:** The nearest opposing clean level with enough room to justify the risk.

Risk and invalidation

- Skip crowded charts where every minor swing is marked
- Skip levels with no hierarchy or no obvious reaction history
- If you cannot tell which level matters most, the chart probably is not clean enough

Recommendation: Use this as a chart-selection rule. If the support or resistance area is not obvious, the trade usually is not either. Cleaner charts typically lead to better decisions and more realistic invalidation points.

Pattern 3 of 9 | Bearish breakdown setup

Descending triangle into support

Bearish breakdown setup

What it signals

A descending triangle shows sellers pressing price into a flat support zone. Lower highs tell you buyers are losing the ability to push back, so repeated tests of the same floor can eventually lead to a breakdown.

Best context

- Flat support is clear and has already been tested multiple times
- Each bounce off support is smaller or shorter-lived
- The broader trend is down, or upside momentum is clearly fading
- There is clean downside space below the support zone

Confirmation checklist

- A body close below support, not just a wick through it
- A failed retest from underneath after the breakdown
- The last lower high stays intact before the short is triggered
- Breakdown works better when support has already been weakened by repeated taps

How to trade it

- **Conservative entry:** Sell the close below support, or a failed retest from below.
- **Aggressive entry:** Enter on the first decisive break if the structure is very mature and the path lower is clear.
- **Protective stop:** Above the last lower high, or above the retest high if entering after the break.
- **First target:** Next support below, or a measured move based on triangle height.

Risk and invalidation

- Skip if support is a major higher-time-frame demand zone with strong reversal history
- Skip if the "breakdown" is only a wick and price immediately reclaims the zone
- Repeated failed breakdowns can lead to violent squeezes back upward

Recommendation: This setup improves when support gets tested several times and buyers cannot create strong bounces anymore. Wait for a real close below the zone - touching support is not enough.

Pattern 4 of 9 | Higher-time-frame retest / old level relevance

Time-away retest of a higher-timeframe level

What it signals

Old weekly or monthly reaction levels can become important again after price spends a long time away from them. The first revisit often attracts more attention because participants remember the prior turning point and have not had many chances to transact there since.

Best context

- The level comes from a clear old swing high or low
- The market has spent weeks or months away from the zone
- The revisit is the first meaningful retest after that long absence
- The level is visible on a higher-time-frame chart

Confirmation checklist

- Fresh rejection or acceptance appears as price revisits the zone
- A strong reversal candle, lower-time-frame trigger, or clean hold develops at the level
- The reaction happens promptly - strong levels usually do not stay "mushy" for long
- The best reactions often come at the first clean return to the level

How to trade it

- **Conservative entry:** Wait for a clear rejection or acceptance candle at the higher-time-frame zone.
- **Aggressive entry:** Fade the first touch only when the level is extremely obvious and the stop can stay tight.
- **Protective stop:** Beyond the rejection wick, or beyond the far side of the zone.
- **First target:** Nearest internal structure level, then the next major swing area.

Risk and invalidation

- Skip if the level is only mid-range noise with no meaningful history
- Skip if price revisits the level repeatedly without a clean reaction
- If there is no clear response on first touch, do not force a trade

Recommendation: Give extra weight to the first revisit of an old higher-time-frame level after long time away. The "time-away" effect often makes the reaction cleaner than a heavily reused level.

Pattern 5 of 9 | Bullish breakout setup

Ascending triangle into resistance

Bullish breakout setup

What it signals

An ascending triangle forms when price keeps making higher lows into a flat resistance ceiling. That structure suggests buyers are getting more aggressive on each dip while sellers keep defending the same price area.

Best context

- A clear flat resistance zone has already been tested
- Pullbacks hold above progressively higher lows
- The triangle is compact and not overly wide or sloppy
- The broader trend already favors the upside

Confirmation checklist

- A decisive close above resistance
- A retest that holds above the former ceiling
- No deep undercut of the last higher low before the break
- Breakout candles show expansion, but not a runaway move far from support

How to trade it

- **Conservative entry:** Buy a close above resistance or the first retest that holds.
- **Aggressive entry:** Enter near the top of the triangle before the break if risk stays small and the pattern is tight.
- **Protective stop:** Below the last higher low, or below the retest low.
- **First target:** Next resistance above, or a measured move based on triangle height.

Risk and invalidation

- Skip if the pattern is too loose, too wide, or full of false breaks
- Skip if price is already extended by the time it clears resistance
- A failed breakout back into the triangle weakens the bullish case quickly

Recommendation: This is strongest when the resistance zone is obvious and each pullback gets bought slightly earlier. In other words, buyers should be bidding higher, not just bouncing randomly inside the range.

Pattern 6 of 9 | Bearish reversal after exhaustion

Resistance rejection after a power move

Bearish reversal setup

**What it signals**

A fast power move into resistance can exhaust short-term buyers. If price then prints a rejection wick and follows with a bearish close, that often shows supply entering where late momentum traders were expecting continuation.

Best context

- The rally into resistance is one-sided and stretched
- Resistance is clearly defined from prior price history
- The move arrives quickly, without long consolidation under resistance
- There is clean room down to the next support level

Confirmation checklist

- A rejection wick or failed push inside the resistance zone
- A bearish close after that rejection
- Follow-through below the rejection low or below the trigger bar
- The setup is stronger if price does not start compressing under resistance

How to trade it

- **Conservative entry:** Short after a bearish close and follow-through from the zone.
- **Aggressive entry:** Fade the rejection wick with smaller size if the level is very obvious.
- **Protective stop:** Above the rejection wick or above the resistance zone.
- **First target:** Next support level, or the midpoint of the prior impulse.

Risk and invalidation

- Skip if price is not stretched and simply starts building under resistance
- Skip if the "rejection" has no follow-through on the next bar
- Strong trends can absorb a single rejection candle and then continue higher

Recommendation: Fade exhaustion, not strength. A fast move into resistance that rejects hard is different from a slow, tight build-up beneath the level. If price starts compressing, the breakout case becomes stronger and the fade becomes weaker.

Pattern 7 of 9 | Bullish reversal after exhaustion

Support rejection after a power move

Bullish reversal setup

What it signals

A sharp selloff into support can create capitulation. When price reaches a clean support zone and prints a hammer or bullish rejection, the market may be showing that sellers have become temporarily exhausted and demand has stepped back in.

Best context

- The decline into support is fast and emotionally one-sided
- Support comes from a clear prior reaction area
- The first bounce happens right at the zone, not far above it
- There is room up to the next resistance area

Confirmation checklist

- Hammer, bullish rejection, or strong bullish close from support
- The next candle holds above the support zone
- The best triggers appear after a power move, not after a slow messy drift
- Volume or spread expansion on the reversal helps the case

How to trade it

- **Conservative entry:** Buy after a bullish close or a successful retest above support.
- **Aggressive entry:** Buy the hammer / rejection low setup with smaller size and a tight stop.
- **Protective stop:** Below the rejection wick or below the far edge of support.
- **First target:** The next resistance area or the midpoint of the drop.

Risk and invalidation

- Skip if the bounce is weak and price closes back under support
- Skip if support has already failed multiple times
- Do not confuse a slow pause in a downtrend with a true rejection

Recommendation: This pattern works best when the move into support feels emotional and stretched. A clean hammer or bullish reclaim gives a better signal than a weak sideways pause at the level.

Pattern 8 of 9 | Caution filter / weak reversal context

Choppy stair-step approach into resistance

A poor reversal setup - opposing pressure is nearby

**What it signals**

A slow stair-step approach into resistance often creates many minor swing lows underneath price. Those nearby lows become potential support on the way down, which crowds the profit path for an immediate reversal short.

Best context

- Use this mainly as a warning, not as a first-touch short trigger
- Price climbs in an overlapping, step-by-step way into resistance
- Minor pullback lows stack closely beneath price
- The market has not shown a sharp exhaustion spike into the level

Confirmation checklist

- Touching resistance alone is not enough
- If you want the short, require strong rejection and a break of several minor supports
- A clean bearish close is more important here than on sharper exhaustion setups
- Without follow-through, the market may simply keep grinding higher

How to trade it

- **Conservative use:** Stand aside until rejection becomes obvious and structure actually breaks.
- **Aggressive use:** If shorting, use smaller size and wait for a decisive bearish trigger.
- **Protective stop:** Above the local high and resistance zone.
- **First target:** The nearest broken minor support, then the next clean support area.

Risk and invalidation

- Skip shorts based only on a touch of resistance
- Skip if the downside path is crowded with nearby higher lows
- This pattern often produces frustrating chop before any real reversal appears

Recommendation: Treat this as a “do not force the fade” setup. The real lesson is that the approach matters: a messy stair-step grind into resistance usually needs extra confirmation before a short makes sense.

Pattern 9 of 9 | Failed breakout / bearish trap

Bull trap above resistance

Failed breakout / bearish reversal

**What it signals**

A bull trap happens when price pokes above obvious resistance, attracts breakout buyers, and then fails back inside the old range. That failed acceptance traps late longs and can accelerate downside as stops begin to get hit.

Best context

- Resistance is obvious and widely visible
- A strong move into the level has already attracted breakout attention
- The breakout above resistance is brief and immediately rejected
- The market closes back below the old breakout line quickly

Confirmation checklist

- Failure close back inside the range
- A retest of the old resistance from underneath that now fails
- Follow-through selling after the trapped breakout traders are exposed
- The trap is stronger when the breakout lacked real acceptance above the zone

How to trade it

- **Conservative entry:** Short the failure close back under resistance or the first failed retest from below.
- **Aggressive entry:** Fade the trap quickly if the reversal is sharp and the stop can stay above the trap high.
- **Protective stop:** Above the trap high or above the failed retest high.
- **First target:** Range midpoint, then next support / opposite side of the prior range.

Risk and invalidation

- Skip if price accepts above resistance and starts holding there
- Skip if the "trap" is only a tiny dip before fresh breakout continuation
- Do not short just because price traded slightly above resistance - the failure back inside the range is the key

Recommendation: This pattern is strongest when the breakout above resistance is obvious enough to pull in late buyers, but brief enough that price never truly accepts above the level. Wait for the failure - not just the poke - before acting.

Execution checklist before taking a trade

These questions are designed to keep the patterns practical. If several answers are weak or unclear, the simplest decision is usually to pass and wait for a cleaner setup.

Pre-trade questions

- Is the support or resistance zone obvious on a zoomed-out chart?
- Is this level on a meaningful time frame, or is it just local noise?
- How is price approaching the level - compressed, impulsive, choppy, or trapped?
- What exact candle close, retest, or structure break confirms the idea?
- Where is the trade invalidated if the market proves me wrong?
- Is there enough room to the first target to justify the risk?
- Am I trading a breakout, a reversal, a retest, or just guessing on first touch?
- If this setup fails, what does that failure imply - reclaim, trap, squeeze, or continuation?

Risk-management reminders

- **Plan the zone first.** Draw the level before price reaches it so the chart does not become reactive and emotional.
- **Wait for the right pattern job.** Tight build-up and triangles favor breakouts; exhaustion and trap behavior favor reversals.
- **Use stops where the idea is actually broken.** Put invalidation beyond the zone or beyond the rejection structure, not at random round numbers.
- **Scale expectations to context.** First target should usually be the next logical level; big targets come only after price proves itself.
- **Passing is a valid decision.** Choppy structure, crowded nearby levels, and weak confirmation are all reasons to stay out.

Final note: Support and resistance works best when the level, the approach, and the trigger all agree. The patterns in this guide are best used as a decision framework: identify the level, classify the approach, wait for confirmation, define invalidation, and take only the trades with clean room to the next target.

1. Draw the zone	2. Classify the approach	3. Wait for confirmation	4. Define stop and target	5. Review follow-through
